

Typical Heating/Cooling Unit.

If the back of the Coil becomes clogged with dirt, then the air can not flow through it. This stops the air from being heated or cooled and also causes less air to flow out to the rooms. If the fins on the fan become loaded with dirt they do not move enough air up to the coil with the same results...poor heating & cooling and poor air flow to the rooms. Many of these units have never been cleaned. Having an HVAC professional clean these 2 areas will really improve system performance, and comfort. This will also cause your motor to run less...saving energy and motor life..
